

What is the pre-charge resistance of the energy storage system

What is a pre-charge resistor?

Pre-charge resistors run the gamut of technology from ceramic and carbon to extruded aluminum and thin film. Pre-charge comes in two flavors. Some designers implement relatively complex pre-charging that happens as part of a power-up sequence. When power consumption is less of a concern, the pre-charging is maintained at all times.

How much power does a precharge resistor dissipate?

The power dissipated by the precharge resistor during precharge is that energy over the precharge time. For example, with a precharge time of 500 ms: $P = V^2 / R = 100^2 / 10 = 1000 \text{ W}$! Now, over the long term, the precharge resistor will not need to dissipate any significant power (it will not get hot).

Do pre-charge components need to be rated for the same voltage?

Pre-charge components must be rated for the same VOLTAGE as the battery. Current requirements are more complex. Brief peak currents are the more critical issue rather than prolonged current-carrying capacity. Resistors, for instance, must handle peak current and dissipate the most heat energy at the start of the pre-charge process.

Does a relay need a precharge resistor?

The relay needs to be able to handle the peak of the inrush current; but, since the average current is low, and the breaking current is nearly zero, the current rating of the relay is not critical. The resistance of the precharge resistor is chosen based on the capacity of the load and the desired precharge time.

How does a pre-charge circuit work?

The pre-charge circuit usually consists of a separate, smaller contactor connected in series with a resistor. These two components are then wired in parallel with the main contactor, typically along the positive side. The resistor's role is to make the charging of the capacitor more gradual.

When should pre-charge be maintained?

When power consumption is less of a concern, the pre-charging is maintained at all times. More complex systems apply pre-charge as part of the starting sequence and will defer main contactor closure until the pre-charge voltage level is detected as sufficiently high.

In order to find inrush current, pre-charge resistor value can be calculated with Eq.(3). In this simulation, pre-charge time is decided as 120 ms and voltage difference between DC-Link ...

The resistance of the precharge resistor is chosen based on the capacity of the load and the desired precharge time. The precharge surge current reaches $1/e$ of its initial value after a time of: $T = R * C$. The current is
